(54) Title: NETWORK CONTENT ACCESS CONTROL

(57) Abstract: A method for preventing unauthorized access by a requestor to data sent via computer networks, including (a) requesting from a requesting computer, access to data from a first server, at the first server (b) determining if the request is a valid request, (c) receiving a ticket from a ticket server, if the request is a valid request, (d) providing the ticket identifying the requestor to a second server the data is stored, (e) directing the requesting computer to request access to the data from the second server, at the second server (f) receiving the request from the requesting computer, (g) verifying the ticket as identifying the requestor, and (h) sending the data to the requesting computer in response to the request.

## NETWORK CONTENT ACCESS CONTROL

### FIELD OF THE INVENTION

The present invention relates to computer network communications in general, and more particularly to preventing unauthorized access to data sent via computer networks.

### BACKGROUND OF THE INVENTION

Methods for controlling access to data via computer networks are well known. Some methods require that IDs and passwords be provided to the data server in order to gain access to data. In other methods a data server provides encrypted data to the client, where the data is then decrypted using a key and decryption software previously provided to the client. In other methods digital watermarks are embedded into the data at the data source allowing for distribution of the data to be monitored for unauthorized distribution.

These and other prior art approaches are suited for peer-to-peer architectures where the data resides at a single source, such as on one or more servers under the direct control of the data owner, and the data is provided directly from the data holder's server to the requesting client. Such peer-to-peer arrangements are currently in wide use on the Internet, and represents the most common default arrangement.

Providing high-bandwidth content via computer networks, however, places a considerable load on peer-to-peer architectures. As a result, proxy servers are often used to "mirror" data stored at the data owner's server and provide data to clients. Unfortunately, these proxy servers are often not under the direct control of the data owner, and steps taken by the data owner at the original data source to protect unauthorized access to data are often not taken by the proxy servers, leading to unauthorized access.

## SUMMARY OF THE INVENTION

The present invention seeks to provide a system for preventing unauthorized access to data sent via computer networks that overcome disadvantages of the prior art.

5           There is thus provided in accordance with a preferred embodiment of the present invention a method for preventing unauthorized access by a requestor to data sent via computer networks, including a) requesting, from a requesting computer, access to data from a first server, at the first server b) determining if the request is a valid request, c) receiving a ticket  
10   from a ticket server, if the request is a valid request d) providing the ticket identifying the requestor to a second server the data is stored, e) directing the requesting computer to request access to the data from the second server, at the second server f) receiving the request from the requesting computer, g) verifying the ticket as identifying the requestor, and h) sending the data to the requesting  
15   computer in response to the request.

Further in accordance with a preferred embodiment of the present invention the requesting computer is a client computer.

Still further in accordance with a preferred embodiment of the present invention the second server is either of a proxy server and a cache  
20   server.

Additionally in accordance with a preferred embodiment of the present invention the data is encrypted and the providing step d) further includes the first server providing a decryption key to the second server for decrypting the data.

25           Moreover in accordance with a preferred embodiment of the present invention the data is encrypted and the providing step d) further includes the ticket server providing a decryption key to the second server for decrypting the data.

Further in accordance with a preferred embodiment of the present invention the providing step d) further includes providing the ticket to  
30

the second server by way of the client computer.

Still further in accordance with a preferred embodiment of the present invention the method further includes the client computer locating the second server using a search engine.

5           Additionally in accordance with a preferred embodiment of the present invention the verifying step g) further includes i) sending the ticket to the ticket server for validation, and j) receiving a communication from the ticket server validating the ticket.

10           Moreover in accordance with a preferred embodiment of the present invention the sending step h) further includes embedding a marking into the data prior to sending the data to the client computer.

Further in accordance with a preferred embodiment of the present invention the marking is a digital watermark.

15           Still further in accordance with a preferred embodiment of the present invention the marking is a personalized marking for the requestor.

20           There is also provided in accordance with a preferred embodiment of the present invention a method for preventing unauthorized transfer of data sent via computer networks, the method including the steps of instructing a first server to send content to a second server, notifying a ticket server of the instructions, validating the instructions at the ticket server, if the instructions are valid notifying either of the servers that the instructions are valid, sending the content from the first server to the second server, if the instructions are invalid notifying either of the servers that the instructions are invalid, performing any of ignoring the instructions, corrupting the content, and  
25           discarding the content.

30           Further in accordance with a preferred embodiment of the present invention the method further includes the steps of embedding a marking into the data, checking the validity of the marking at either of the servers, and if the marking is invalid, performing any of ignoring the instructions, corrupting the content, and discarding the content.

Still further in accordance with a preferred embodiment of the present invention the validating step includes validating the instructions in accordance with a policy.

5 Additionally in accordance with a preferred embodiment of the present invention the embedding step includes embedding any of an identification unique to the first server, an identification unique to the second server, routing information, and rule-based information.

10 Moreover in accordance with a preferred embodiment of the present invention the method further includes the first server receiving an encryption key from the ticket server, and encrypting the content using the encryption key.

15 Further in accordance with a preferred embodiment of the present invention the method further includes the second server receiving a decryption key from either of the first server and the ticket server, and decrypting the content using the decryption key.

According to a third aspect of the present invention there is provided a data transfer validation server for validating a request for data transfer, the server comprising:

20 a request input for receiving a request from a distribution server to distribute data from said distribution server to a requesting client,

a distribution parameter table comprising predetermined distribution parameters,

a comparator for comparing said request against said predetermined distribution parameters,

25 a verifier connected to said comparator for verifying said request, at least partly in accordance with an output of said comparator, and

a ticket issuer for issuing ticket data indicating acceptance of said request.

30 Preferably, said predetermined distribution parameters comprise approved times for providing content.

Additionally or alternatively, the predetermined distribution parameters comprise approved regions for providing content.

Additionally or alternatively, the predetermined distribution parameters comprise approved distribution portals.

5        Additionally or alternatively, the predetermined distribution parameters comprise approved users.

Additionally or alternatively, the predetermined distribution parameters comprise non-approved distribution portals.

10       Additionally or alternatively, the predetermined distribution parameters comprise non-approved users.

Additionally or alternatively, the predetermined distribution parameters comprise different parameters for content items from different content sources.

Additionally or alternatively, the predetermined distribution parameters comprise different parameters for different content items.

15       Additionally or alternatively, the predetermined distribution parameters comprise a requirement for an endpoint rights protection scheme.

### BRIEF DESCRIPTION OF THE DRAWINGS

20       The present invention will be understood and appreciated more fully from the following detailed description taken in conjunction with the appended drawings in which:

25       Fig. 1 which is a simplified conceptual illustration of a system for preventing unauthorized access to data sent via computer networks, constructed and operative in accordance with a preferred embodiment of the present invention;

Fig. 2 is a simplified flowchart illustration of a method of operation of the system of Fig. 1, the method being operative in accordance with a preferred embodiment of the present invention;

30       Fig. 3 is a simplified conceptual illustration of a system for preventing unauthorized transfer of data sent via computer networks,

constructed and operative in accordance with another preferred embodiment of the present invention; and

Fig. 4 is a simplified flowchart illustration of a method of operation of the system of Fig. 3, operative in accordance with a preferred embodiment of the present invention;

## DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Reference is now made to Fig. 1, which is a simplified conceptual illustration of a system for preventing unauthorized access to data sent via computer networks, constructed and operative in accordance with a preferred embodiment of the present invention. In the system of Fig. 1, data, such as text-based or numeric data, graphical data, audio data, or any other kind or combination of data that may be transmitted via a computer network, is stored on a server 10, such as a proxy or cache server, typically provided to server 10 by a data source server 12, such as via a computer network 14, such as the Internet. Preferably, the data provided by server 12 to server 10 is encrypted using any conventional encryption technique.

A ticket server 18 provides data transfer verifications hereinafter referred to as tickets, to server 12, such as via network 14, where each ticket includes an identifier that is preferably unique to all other tickets provided to server 12 and/or all other tickets provided by server 18 to any other server, and that is preferably encrypted using any conventional encryption technique. Tickets may be provided to server 12 in response to a request sent by server 12 to server 18 for tickets, such as upon server 12 receiving a request from a user at a client computer 16 who wishes to access the data stored on server 10, and/or may be provided not in connection with any such request, such as for future use by server 12. Client computer 16 may be any network-connectable computer or appliance, such as a personal computer, a personal digital assistant, a cellular telephone, and a web-enabled television appliance.

A typical operational scenario of the system of Fig. 1 may be seen with additional reference to Fig. 2, which is a simplified flowchart illustration of a method operative in accordance with a preferred embodiment of the present invention. In the method of Fig. 2 a user at client computer 16 who  
5 wishes to access the data stored on server 10 sends a request to server 12 to access the data, such as via network 14 (step 100). Server 12 identifies the user using any conventional technique, such as by a user identifier sent with the request or by the source address of the request being previously known to server 10 (step 110), and determines whether the user is authorized to access the data  
10 (step 120). This authorization process may include checking the user's current credit status or account balance or any other known authorization criteria (or other methods in use today). If the user is authorized to access the data, server 12 requests a ticket from ticket server 18 (step 130). Alternatively or additionally, server 12 may request or otherwise receive one or more tickets  
15 prior to receiving requests from clients. The ticket, preferably encrypted, is sent by server 12 to server 10 together with a user and/or client computer identifier identifying the requestor and preferably a decryption key, where the data at server 10 is encrypted (step 140). Alternatively, the key may be provided to server 10 by ticket server 18 as part of the verification process (see step 180  
20 below). Client 16 is then directed to server 10, typically by server 12, which client 16 then contacts (step 150). Alternatively, server 10 or another server on client 16's request route may intercept the client 16's request and redirect client 16 to server 10. Yet another possibility is where client 16 receives ticket 20 from server 12 and searches for the most suitable server, in terms of distance,  
25 load and other parameters, where the desired data may be found. In this case, once client 16 locates an appropriate server 10 it sends ticket 20 to server 10 which validates it with server 18 and transmits the content to client 16.

Upon being contacted by client 16, server 10 identifies the requesting user using any conventional technique, such as by a user identifier  
30 sent with the request or by the source address of the request being previously

known to server 10, and searches for a ticket bearing the user's identity (step 160). Server 10 then sends information from the ticket, such as the ticket identifier and/or the user identifier, or the entire ticket 20 to ticket server 18 for verification (step 170). Ticket server 18 then verifies the ticket (step 180),  
5 preferably taking steps that the ticket either be cancelled or removed from the ticket pool (such as in the case where client 16's access to the data is limited) or allowed to remain at ticket server 18 (such as where client 16's access to the data is unlimited). Ticket server 18 then notifies server 10 that the ticket is valid (step 190). Server 10 then decrypts the data if required using the decryption key  
10 received with the ticket (step 200), and sends the data to the user at client 16 (step 210). Optionally, server 10 may, using conventional techniques, embed a digital watermark or any other type of known marking into the data before it is sent to client 16. The embedded marking may be sent to server 10 as part of ticket 20. The digital watermark may be personalized for the specific user.  
15 Server 10 may also encrypt the data before it is sent to client 16, with the decryption key having been previously sent to client 16 by server 12 as part of the redirect message or otherwise.

Alternatively to step 140, server 12 may send the ticket to client 16 in addition to or instead of sending the ticket to server 10. Where the ticket is  
20 sent to client 16, client 16 provides the ticket to server 10 which then verifies the ticket with ticket server 18 as described hereinabove. Where server 12 does not provide redirection information to client 16, server 12 may provide other information to client 16, such as keywords identifying server 10, that client 16 may then use to search for server 10 (which has the required content) using  
25 conventional techniques, such as by using publicly-available search engines.

Verification step 180 may include determining the validity of the ticket in accordance with a policy table 8, which typically includes distribution parameters preferably specified by the content owner. Examples of such distribution parameters may include approved times for providing content,  
30 approved sources of specific content, types of end-point protection schemes

required (such as Microsoft Digital Rights Management, Intertrust DigiBox, etc.), as well as a list of unauthorized set-top boxes, and users. Examples of policies may include:

- Example I: The KickBox portal is not authorized to sell Disney movies.
- Example II: A user which is located in Belgium (region 2), is not authorized to receive/view Star Wars 8, which is currently authorized for users in region 1 only.

Encryption keys referred to hereinabove may be alternatively provided by client 16 to server 10 for encrypting data prior to transmission to client 16. The keys may be preconfigured with client 16 or generated by client 16 using conventional software techniques. Furthermore, decryption keys referred to hereinabove that are sent to client 16 may be likewise preconfigured with client 16, thus obviating the need to transmit decryption keys to client 16.

Reference is now made to Fig. 3, which is a simplified conceptual illustration of a system for preventing unauthorized transfer of data sent via computer networks, constructed and operative in accordance with another preferred embodiment of the present invention, and additionally to Fig. 4, which is a simplified flowchart illustration of a method of operation of the system of Fig. 3, operative in accordance with a preferred embodiment of the present invention. In the system of Fig. 3 and method of Fig. 4 authorized content 30 resides on a server 32, such as a proxy or cache server. A content delivery controller 36, such as a server, instructs server 32 to send content 30 to a server 34 (step 300). Controller 36 may be configured to determine the current network load on servers 32 and 34 using conventional load balancing techniques, instructing server 32 to send content 30 to server 34 in order to redistribute the load in accordance with predefined load balancing criteria. A ticket server 38 is notified of the transfer instructions, either by server 36 or by server 32 (step 310). Ticket server 38 preferably checks the validity of the transfer parameters against a policy table 40 (step 320). Server 32 and/or server

34 are notified of the validity of the instructions by ticket server 38 (step 330), with server 32 and/or server 34 ignoring the instructions should they be proven invalid (step 340). Server 36 may also be notified of the instructions not having been carried out by server 32, 34, or 38.

5 Ticket server 38 may send a ticket to server 32 and/or server 34 in anticipation of the transfer of content 30 (step 350). Prior to sending content 30 to server 34, server 32 preferably embeds into content 30, using digital watermarking or other known data embedding technique, an identification unique to server 32, an identification unique to server 34, and/or other routing  
10 and/or rule-based data, such as "do not pass through a specific region" where the region is identified by routers or proxies along the way (step 360). Server 32 preferably encrypts content 30 using an encryption key that server 32 receives as part of the ticket sent to it by ticket server 38 (step 370). Server 32 then sends content 30 to server 34 (step 380) and preferably reports to ticket server 38 that  
15 content 30 was sent to server 34 (step 390).

Content 30 then arrives at server 34. If content 30 is encrypted server 34 may decrypt it, preferably with a decryption key received from ticket server 38 (step 400). Server 34 then determines that content 30 is allowed to reside on server 34 by checking the validity of content 30's embedded  
20 information (step 410). If content 30 lacks a correctly encoded digital watermark, or if the information embedded into content 30 otherwise contraindicates a valid content transfer, then content 30 is deemed to be invalid. Additionally or alternatively, server 34 may send a ticket to ticket server 38 with content 30's ID for validation. If either server 34 or ticket server 38 determine  
25 that content 30 is improperly marked or otherwise identified, server 34 discards content 30 (step 420). Server 34 and subsequent servers may similarly mark and encrypt content 30 prior to sending content 30 to another server.

The watermarking of content 30 in accordance with conventional techniques is preferably done such that if content 30 is modified,  
30 the watermark in content 30 will change. Thus, if server 34 does not identify a

proper digital watermark in content 30, or if server 34 determines that the watermark has been removed, content 30 is discarded.

As an alternative to discarding unauthorized content, the content may simply be corrupted and thus rendered useless. It is appreciated that either  
5 technique may be implemented at suitable configured servers or at routers capable of being configured to perform the method of Fig. 4.

It is appreciated that content that is received from a server in accordance with the present invention may identify the particular server from which it came where the digital watermark embedded by the server is unique to  
10 that server. Thus, any attempt to store content on a server in an unauthorized fashion will result in the content being discarded or corrupted in accordance with the method of Fig. 4.

The validity of a ticket may be determined in accordance with policy table 40 including distribution parameters preferably specified by the  
15 content owner and implemented at ticket server 38. Examples of such distribution parameters may include allowing only proxies located at specific geographical regions to receive and/or supply content, as well as a list of unauthorized servers, or servers whose security has been compromised. Examples of policies may include a server which is located in Italy (region 2) is  
20 not authorized to contain Star Wars 8, which is currently authorized for region 1 servers only.

It is appreciated that functional elements of the invention described herein with respect to a specific server may be incorporated into any other of the servers mentioned herein in accordance with conventional  
25 techniques.

It is appreciated that one or more steps of any of the methods described herein may be implemented in a different order than that shown while not departing from the spirit and scope of the invention.

While the methods and apparatus disclosed herein may or may  
30 not have been described with reference to specific hardware or software, the

methods and apparatus have been described in a manner sufficient to enable persons of ordinary skill in the art to readily adapt commercially available hardware and software as may be needed to reduce any of the embodiments of the present invention to practice without undue experimentation and using  
5 conventional techniques.

While the present invention has been described with reference to a few specific embodiments, the description is intended to be illustrative of the invention as a whole and is not to be construed as limiting the invention to the embodiments shown. It is appreciated that various modifications may occur  
10 to those skilled in the art that, while not specifically shown herein, are nevertheless within the true spirit and scope of the invention.

What is claimed is:

1. A method for preventing unauthorized access by a requestor to data sent via computer networks, comprising:

5 a) requesting, from a requesting computer, access to data from a first server;

at said first server:

b) determining if said request is a valid request;

c) receiving a ticket from a ticket server;

10 if said request is a valid request:

d) providing said ticket identifying said requestor to a second server wherein said data is stored;

e) directing said requesting computer to request access to said data from said second server;

15 at said second server:

f) receiving said request from said requesting computer;

g) verifying said ticket as identifying said requestor; and

h) sending said data to said requesting computer in response to said request.

20 2. A method according to claim 1 wherein said requesting computer is a client computer.

3. A method according to claim 1 wherein said second server is  
25 either of a proxy server and a cache server.

4. A method according to claim 1 wherein said data is encrypted and wherein said providing step d) further comprises said first server providing a decryption key to said second server for decrypting said data.

5. A method according to claim 1 wherein said data is encrypted and wherein providing step d) further comprises said ticket server providing a decryption key to said second server for decrypting said data.

5 6. A method according to claim 1 wherein said providing step d) further comprises providing said ticket to said second server by way of said client computer.

7. A method according to claim 6 and further comprising said  
10 client computer locating said second server using a search engine.

8. A method according to claim 1 wherein said verifying step g) further comprises:

i) sending said ticket to said ticket server for validation; and  
15 j) receiving a communication from said ticket server validating said ticket.

9. A method according to claim 1 wherein said sending step h) further comprises embedding a marking into said data prior to sending said data  
20 to said client computer.

10. A method according to claim 9 wherein said marking is a digital watermark.

25 11. A method according to claim 9 wherein said marking is a personalized marking for said requestor.

12. A method for preventing unauthorized transfer of data sent via computer networks, the method comprising the steps of:  
30 instructing a first server to send content to a second server;

notifying a ticket server of said instructions;

validating said instructions at said ticket server;

if said instructions are valid:

notifying either of said servers that said instructions are

5 valid;

sending said content from said first server to said second

server;

if said instructions are invalid:

notifying either of said servers that said instructions are

10 invalid;

performing any of:

ignoring said instructions;

corrupting said content; and

discarding said content.

15

13. A method according to claim 12 and further comprising the steps of:

embedding a marking into said data;

checking the validity of said marking at either of said servers;

20 and

if said marking is invalid, performing any of:

ignoring said instructions;

corrupting said content; and

discarding said content.

25

14. A method according to claim 12 wherein said validating step comprises validating said instructions in accordance with a policy.

15. A method according to claim 14, wherein said policy is  
30 comprised in a distribution policy table.

16. A method according to claim 15, said distribution policy table comprising predetermined distribution parameters.

5 17. A method according to claim 16, table said validating step comprises validating said instructions by comparing parameters of said instructions with said distribution parameters of said distribution policy table.

10 18. A method according to claim 16, wherein said predetermined distribution parameters comprise approved times for providing content.

19. A method according to claim 16, wherein said predetermined distribution parameters comprise approved regions for providing content.

15 20. A method according to claim 16, wherein said predetermined distribution parameters comprise approved distribution portals.

20 21. A method according to claim 16, wherein said predetermined distribution parameters comprise approved users.

22. A method according to claim 16, wherein said predetermined distribution parameters comprise non-approved distribution portals.

25 23. A method according to claim 16, wherein said predetermined distribution parameters comprise non-approved users.

24. A method according to claim 16, wherein said predetermined distribution parameters comprise different parameters for content items from different content sources.

25. A method according to claim 16, wherein said predetermined distribution parameters comprise different parameters for different content items.

5 26. A method according to claim 16, wherein said predetermined distribution parameters comprise a requirement for an endpoint rights protection scheme.

10 27. A method according to claim 13 wherein said embedding step comprises embedding any of an identification unique to said first server, an identification unique to said second server, routing information, and rule-based information.

15 28. A method according to claim 12 and further comprising:  
said first server receiving an encryption key from said ticket server; and  
encrypting said content using said encryption key.

20 29. A method according to claim 28 and further comprising:  
said second server receiving a decryption key from either of said first server and said ticket server; and  
decrypting said content using said decryption key.

25 30. A data transfer validation server for validating a request for data transfer, the server comprising:  
a request input for receiving a request from a distribution server to distribute data from said distribution server to a requesting client,  
a distribution parameter table comprising predetermined  
30 distribution parameters,

a comparator for comparing said request against said predetermined distribution parameters,

a verifier connected to said comparator for verifying said request, at least partly in accordance with an output of said comparator, and

5 a ticket issuer for issuing ticket data indicating acceptance of said request.

31. A data transfer validation server according to claim 30, wherein said predetermined distribution parameters comprise approved times for  
10 providing content.

32. A data transfer validation server according to claim 30, wherein said predetermined distribution parameters comprise approved regions for  
15 providing content.

33. A data transfer validation server according to claim 30, wherein said predetermined distribution parameters comprise approved distribution  
portals.

20 34. A data transfer validation server according to claim 30, wherein said predetermined distribution parameters comprise approved users.

35. A data transfer validation server according to claim 30, wherein said predetermined distribution parameters comprise non-approved distribution  
25 portals.

36. A data transfer validation server according to claim 30, wherein said predetermined distribution parameters comprise non-approved users.

30 37. A data transfer validation server according to claim 30, wherein

said predetermined distribution parameters comprise different parameters for content items from different content sources.

38. A data transfer validation server according to claim 30, wherein  
5 said predetermined distribution parameters comprise different parameters for different content items.

39. A data transfer validation server according to claim 30, wherein  
said predetermined distribution parameters comprise a requirement for an  
10 endpoint rights protection scheme.

40. A data transfer validation server according to claim 30, said predetermined distribution parameters being user specifiable.

(54) Title: NETWORK CONTENT ACCESS CONTROL

(57) Abstract: A method for preventing unauthorized access by a requestor to data sent via computer networks, the method including the steps of: requesting (100), from a requesting computer, access to data from a first server, at the first server: determining (110,120) if the request is a valid request; receiving (130,140) a ticket from a ticket server if the request is a valid request; providing the ticket identifying the requestor to a second server wherein the data is stored; and directing (150) the requesting computer to request access to the data from the second server; and at the second server: receiving the request from the requesting computer; verifying (160,170,180,19) the ticket as identifying the requestor; and sending (200,210) the data to the requesting computer in response to the request.

## INTERNATIONAL SEARCH REPORT

International application No.

PCT/IL01/00324

**A. CLASSIFICATION OF SUBJECT MATTER**

IPC(7) : H04L 9/00, 9/02; G06F 17/30

US CL : 713/155, 156, 176, 200, 201; 709/219, 229

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 713/155, 156, 176, 200, 201; 709/219, 229

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

STN. EAST

search terms: redirecting, client, server, authentication, access control, ticket

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 5,509,074 A (CHOUDHURY et al.) 16 April 1996, Figures 3 and 4, col. 5 and col. 5.	1-5, 8-11, 12-29
Y		6, 7
X	US 5,506,961 A (CARLSON et al.) 09 April 1996, Abstract, Figure 3, col. 2, col. 3-4, col. 6.	30-40
Y	US 5,948,061 A (MERRIMAN et al) 07 September 1999, Abstract, Figure 1, columns 3-5.	6 and 7

☐ Further documents are listed in the continuation of Box C.
 ☐ See patent family annex.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier document published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Z" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed
